be taken, however, as a binary distinction.

As for (1), the distinction between (a) and (b) is also that of "illustration" and "representation," which must not simply be glossed over. "Illustration" and "representation" carry with them the difference between their former ("illustration") and new ("simulation") status. It is thus the difference between (a) and (b) that carries the distinction between their former status and the new status. The distinction between (a) and (b) is thus a binary one.

The most interesting distinction between the two senses of "illustration" is that it has been simplified. (1) is not used in (a) as a substitute for (b), and vice versa. (b) does not mean "decomposition," but it is used in (1) as a substitute for (b).

Correspondence (1) is equivalent to (a) in its "true" sense in (1).

Notice that in the portrayal sense of (1), the reflection moves along the image plane, while in the representation sense of (1), the reflection moves along the image plane.
The Process of Comparing

There is another spatial proposition that exhibits the idea of distance. If, as in (18), the distance is presented as a certain measure, the district boundaries are represented as lines of equal distance. The process of comparing involves the comparison of these distances, which is performed by an operator that takes part in the process of comparing. The relation proposed by between implies the existence of the distance, which takes place in the process of comparing. The relation proposed by between implies the existence of the distance, which takes place in the process of comparing.
The Process of Comparing.
The Process of Comparing

comparison, volleys, current background, and other considerations depends to a large extent on the interaction of the activity of the subject with the environment. The subject's ability to compare effectively is influenced by the nature of the task and the environment in which it is performed. The more effective the subject's ability to compare, the more likely it is that the comparison will be successful.

In a narrow zone of the brain or language, the comparison process is a typical phenomenon in which a group of neurons is activated by a specific stimulus. The comparison process is not limited to the brain, but it can occur in any part of the body, including the muscles, the heart, and the skin.

In order to find an optimal solution, for example, processors may use comparisons. Two or more comparisons can be carried out at the same time in some cases. There can be many different types of comparison, depending on the purpose of the comparison and the characteristics of the objects being compared. In general, comparisons are always made between two sets of values, under comparison, and the results of the comparison are taken into consideration when making a decision.

3. Partial Perception

By the very act of perception, the brain is able to process a wide range of information. In a narrow zone of the brain or language, the comparison process is a typical phenomenon in which a group of neurons is activated by a specific stimulus. The comparison process is not limited to the brain, but it can occur in any part of the body, including the muscles, the heart, and the skin.
